Abstract—A novel design procedure of equiripple half-band FIR filters is developed. Solution of the approximation problem in terms of generating function and zero phase transfer function for the equiripple half-band FIR filter is presented. The equiripple half-band FIR filters are optimal in the Chebyshev sense. The generating function for the equiripple half-band FIR filter is presented. The closed form solution provides an efficient computation of the impulse response of the filter. One example is included.

Keywords—FIR filter, half-band filter, equiripple approximation, optimal filter.

I. INTRODUCTION

Half-band (HB) filters are fundamental building blocks in multirate signal processing. They are used e.g. in filter banks and in compression techniques. The only available method for designing of equiripple (ER) HB FIR filters is based on the numerical McClellan - Parks program [1]. It is usually combined with a clever “Trick” [2]. Besides this, some design methods are available for almost ER HB FIR filters, e.g. [3], [4]. No general non-numerical design of an ER HB FIR filter was found in the references. In our paper we are primarily concerned with the ER approximation of HB FIR filters and with the related non-numerical design procedure suitable for practical design of ER HB FIR filters. We present the generating function and the zero phase transfer function of the ER HB FIR filter. These functions give an insight into the nature of this approximation problem. Based on the differential equation for the Chebyshev polynomials of the second kind, we have derived formulas for an effective evaluation of the coefficients of the impulse response. We present an approximating degree equation that is useful in practical filter design. The advantage of the proposed approach over the numerical design procedures consists in the fact that the coefficients of the impulse response are evaluated by formulas. Hence the speed of the design is deterministic.

II. IMPULSE RESPONSE, TRANSFER FUNCTION AND ZERO PHASE TRANSFER FUNCTION

An HB filter is specified by the minimal passband frequency \( \omega_p \) (or maximal stopband frequency \( \omega_s \)) and by the minimal attenuation in the stopband \( a_s \) [dB] (or maximal attenuation in the passband \( a_p \) [dB]). The antisymmetric behavior of its frequency response implies the relations \( \omega_p + \omega_s = \pi \) and \( 10^{a_p/20} + 10^{a_s/20} = 1 \). The goal in the filter design is to get the minimum filter length \( N \) satisfying the filter specification and to evaluate the coefficients of the impulse response of the filter. We assume the impulse response \( h(k) \) with odd length \( N = 2(2n+1) + 1 \) coefficients and with even symmetry \( h(k) = h(N-1-k) \). The impulse response of the HB FIR filter contains \( 2n \) zero coefficients as follows

\[
\begin{align*}
  h(2n+1) &= a(0) = 0.5 \\
  2h(2n+1 \pm 2k) &= a(2k) = 0, k = 1 \ldots n \\
  2h(2n+1 \pm (2k+1)) &= a(2k+1), k = 0 \ldots n.
\end{align*}
\]

The transfer function of the HB FIR filter is

\[
H(z) = \frac{1}{2} \sum_{k=0}^{2n} a(2k+1) T_{2k+1}(\omega) \]

where \( T_i(w) \) is Chebyshev polynomials of the first kind.

The frequency response \( H(e^{j\omega}) \) of the HB FIR filter is

\[
H(e^{j\omega}) = e^{-j(2n+1)\omega} Q(\cos \omega) \]

where \( Q(w) \) is a polynomial in the variable \( w = (z + z^{-1})/2 \) which on the unit circle reduces to a real valued zero phase transfer function \( Q(w) \) of the real argument \( w = \cos(\omega) \).

III. GENERATING POLYNOMIAL AND ZERO PHASE TRANSFER FUNCTION OF AN ER HB FIR FILTER

The generating polynomial of an ER HB FIR filter is related to the generating polynomial of the almost ER HB FIR filter presented in [4]. Based on our experiments conducted in [4], we have found that the generating polynomial \( g(w) \) (Fig.1) of the ER HB FIR filter is obtained by weighting of Chebyshev polynomials in the generating polynomial of the almost ER HB FIR filter, namely

53
Figure 1. Generating polynomial $G(w)$ for $n=20$, $\kappa' = 0.03922835 , A=1.08532371$ and $B=0.95360863$

$G(w) = AU_n\left(\frac{2w^2 - 1 - \kappa'^2}{1 - \kappa'^2}\right) + BU_{n-1}\left(\frac{2w^2 - 1 - \kappa'^2}{1 - \kappa'^2}\right)$

(4)

where $U_n(x)$ and $U_{n-1}(x)$ are Chebyshev polynomials of the second kind and $A$, $B$, $\kappa'$ are real numbers. The zero phase transfer function $Q(w)$ (Fig. 2) is related to the generating polynomial

$Q(w) = \frac{1}{2} + \frac{1}{N} \int G(w) dw$

(5)

where the norming factor $N$ is given by (17). Both the generating polynomial $G(w)$ and the zero phase transfer function $Q(w)$ show the nature of the approximation of an ER HB FIR filter.

IV. DIFFERENTIAL EQUATION AND IMPULSE RESPONSE OF AN ER HB FIR FILTER

The Chebyshev polynomial of the second kind $U_n(x)$ fulfills the differential equation

$(1-x^2)\frac{d^2U_n(x)}{dx^2} - 3x\frac{dU_n(x)}{dx} + n(n+2)U_n(x) = 0$.

(6)

Using substitution

$x = \left(\frac{2w^2 - 1 - \kappa'^2}{1 - \kappa'^2}\right)$

(7)

we get the differential equation (6) in the form

$w(w^2 - \kappa'^2)\left[ (1-w^2) \frac{d^2U_n(w)}{dw^2} - 3w \frac{dU_n(w)}{dw} \right]$

$+ (\kappa'^2 - 1 - w^2) \frac{dU_n(w)}{dw} + 4w^2n(n+2)U_n(w) = 0$.

Based on the differential equation (8), we have derived the non-numerical procedure for the evaluation of the impulse response $h_t(k)$ corresponding to polynomial $\tilde{U}_n(w)$

$\tilde{U}_n(w) = \int U_n\left(\frac{2w^2 - 1 - \kappa'^2}{1 - \kappa'^2}\right) dw$.

(9)

This procedure is summarized in Tab.1. The impulse response $h(k)$ of the ER HB FIR filter is

$h(k) = \frac{1}{N} h_n(k) + \frac{B}{N} h_{n-1}(k)$.

(10)

The non-numerical evaluation of the impulse response $h(k)$ is essential in the practical filter design.

V. DEGREE OF AN ER HB FIR FILTER

The exact degree formula is not available. In the practical filter design, the degree $n$ can be obtained with excellent accuracy from the specified minimal passband frequency $\omega_p, T$ and from the minimal attenuation in the stopband $a_s$ [dB] using the approximating degree formula

$n \geq a_s[\text{dB}] - 18.8840664\omega_p T + 33.64775300$ \(\frac{18.54155181\omega_p T - 29.13196871}{18.54155181\omega_p T + 29.13196871}$

(11)
The exact relation between the minimal attenuation in the stopband $\alpha_s$ [dB], the minimal passband frequency $\omega_p$ and the degree $n$ were obtained experimentally. It is shown in Fig.3. Equation (11) was obtained by the approximation of exact experimental values in Fig.3.

VI. SECONDARY VALUES OF THE ER HB FIR FILTER

The secondary real values $\kappa'$, $A$ and $B$ can be obtained from the specified passband frequency $\omega_p T$ and from the degree $n$ of the generating polynomial. In practical filter design, the approximating formulas

$$\kappa' = \frac{n \omega_p T - 1.57111377n + 0.00665857}{-1.01927560n + 0.37221484}$$

$$A = \left(0.01525753n + 0.036823440 + \frac{9.24760134}{n}\right) \kappa'$$

$$B = \left(0.00233667n - 1.35418408 + \frac{5.75145813}{n}\right) \kappa'$$

obtained experimentally provide excellent accuracy. Further, the exact values $\kappa'$, $A$ and $B$ can be obtained numerically (e.g. using the Matlab function fminsearch) by satisfying the equality (see Fig.4)

$$Q(w_p) = \begin{cases} Q(l) & \text{if } n \text{ is odd} \\ Q(w_{01}) & \text{if } n \text{ is even.} \end{cases}$$

The value

$$w_{01} = \sqrt{\kappa'^2 + (1 - \kappa'^2) \cos^2 \frac{\pi}{2n + 1}}$$

was introduced in [4]. Relation (15) guarantees the equiripple behaviour of the generating polynomial $Q(w)$.

VII. DESIGN OF THE ER HB FIR FILTER

The design procedure is as follows:

- Specify the ER HB FIR filter by the minimal passband frequency $\omega_p T$ and by the minimal attenuation in the stopband $\alpha_s$ [dB].
- Calculate the integer degree $n$ of the generating polynomial (11).
- Calculate the real values $\kappa'$ (12), $A$ (13) and $B$ (14).
- Evaluate the partial impulse responses $h_s(k)$ and $h_{s+1}(k)$ (Tab.1).
- Evaluate the final impulse response $h(k)$ (10) where the real norming factor $\tilde{N}$ is

$$\tilde{N} = \begin{cases} 2A\tilde{U}_s(1) + B\tilde{U}_{s+1}(1) & \text{if } n \text{ is even} \\ 2A\tilde{U}_s(\omega_0) + B\tilde{U}_{s+1}(\omega_0) & \text{if } n \text{ is odd.} \end{cases}$$

VIII. EXAMPLE

Design the ER HB FIR filter specified by the minimal passband frequency $\omega_p T = 0.45\pi$ and by the minimal attenuation in the stopband $\alpha_s = -120$dB.

We get $n = 38.3856 \rightarrow 39$ (11), $\kappa' = 0.15571103$ (12), $A = 1.17117396$ (13), $B = 0.38763199$ (14) and $\tilde{N} = -2747.9638544$ (17). The impulse response $h(k)$ (Tab.2) with the length N=159 coefficients is evaluated using Tab.1 and (10). The actual values $\omega_{p,av} T = 0.4502\pi$ and $\alpha_{av} = -120.91$ dB satisfy the filter specification. The amplitude frequency response $20\log[H(e^{\omega T})]$ [dB] of the filter is shown in Fig.5. The detailed view of its passband is shown in Fig.6. For the specified values $\omega_p T = 0.45\pi$ and N=159, the comparative numerical design based on the "Trick" [2]

Combined with the Remez algorithm using the Matlab function `firpm` results in the slightly unsatisfactory minimal passband frequency \( \omega_p = 0.44922001 \pi < 0.45\pi \) and consequently in a slightly better minimal attenuation in the stopband \( \alpha_{min} = -123.29066608 \) [dB].
